Lwandiso George
Livhu
Njabulo

TASK 7

Design change 1: Separating the observer and the Builder

The problem:

Do we want to couple the builder to know all the state of the products or do we want it to just know about the product that it is supposed to build from.

The original design:

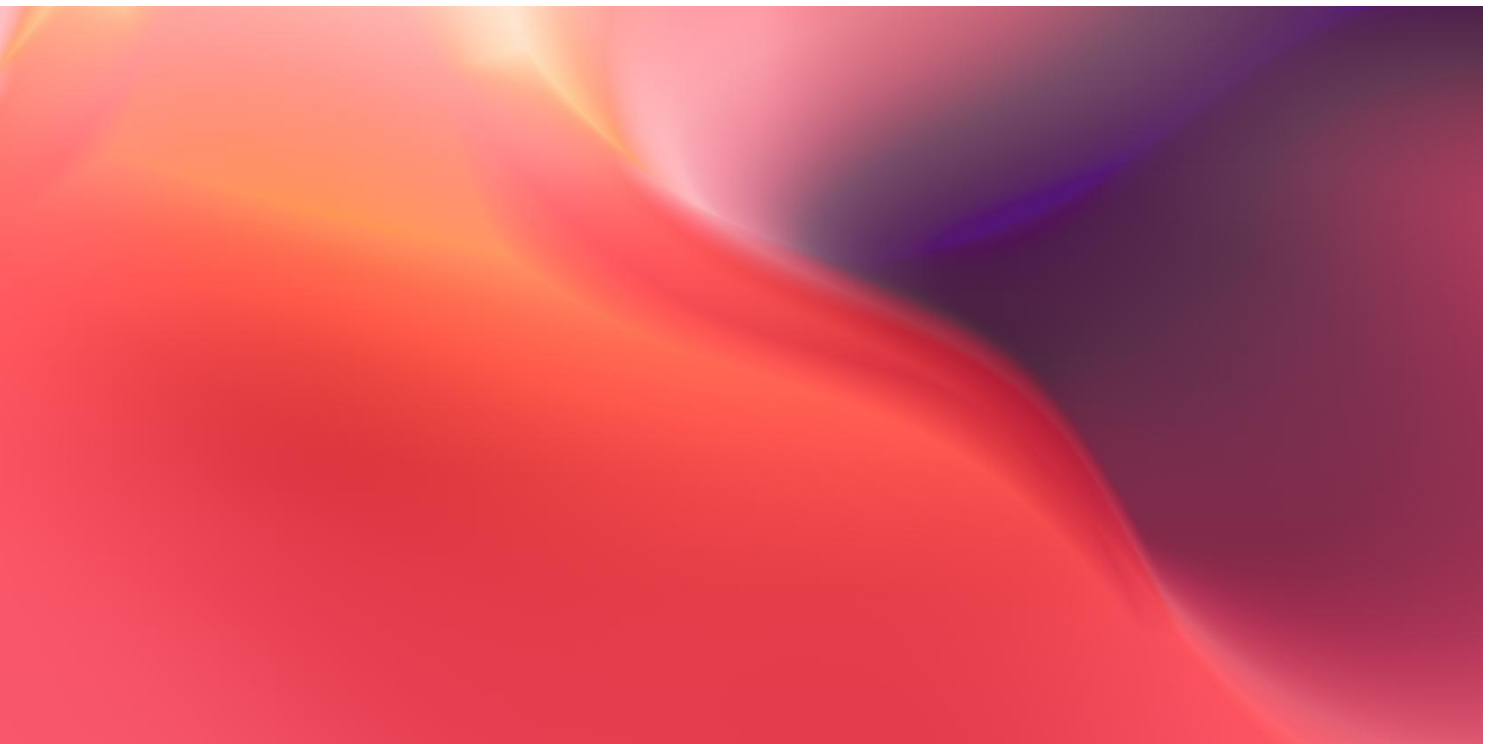

The Observer and the Builder were one combined class.

The change made:

We separated the Builder and the Observer. Making them their own separate classes.

Updates to relevant diagrams:

The change was made before other diagrams being made; hence the only modification was to the class diagram.

Design change 2: Adding an abstract layer between component and the composite

The problem:

Do we want to make all inheriting classes aggregates, or only the one that contains an aggregation.

The original design:

The component was an abstract aggregate, and its leaves, i.e. leaves and composite where concrete aggregates.

The change made:

We added an extract abstract layer between the component and the composite and made it the abstract aggregate.

Updates to relevant diagrams:

The change was made before other diagrams being made; hence the only modification was to the class diagram.
